Looks like Chris_g had some useful input. This is where experience counts, which I don't have. There's no one size fits all approximation scheme, which is why all these tuning options are provided. This is good when you have some specific data to fit, but you are trying to make a general routine...
It looks to me some of your curves are piecewise smooth. Fitting routines might do better if there was a way to break the curve up into its smooth components and join their fits together, but if this comes from mesh data, that information is likely lost.
Not much help I'm afraid.

I am adding a point and a coincident point where I think there should be separate curves before processing. It is having made a separate set of lines, I need to have it fit an Open BSpline, not sure Open is the correct term, a BSpline that has two ends not a closed shape. For sets of lines that make up a closed shape I do not try and separate and approximate does not produce oddities
